

1. Electrical Blackbox: Capacitive Displacement Sensor

For a capacitor of capacitance C which is a component of a relaxation oscillator whose frequency of oscillation is f , the relationship between f and C is as follows:

$$f = \frac{\alpha}{C + C_s}$$

where α is a constant and C_s is the stray capacitance of our circuits. The frequency f can be monitored using a digital frequency meter.

The electrical blackbox given in this experiment is a parallel plate capacitor. Each plate consists of a number of small teeth of the same geometrical shape. The value of C can be varied by displacing the upper plate relative to the lower plate, horizontally. Between the two plates there is a sheet of dielectric material.

Equipment: a relaxation oscillator, a digital multimeter for measuring frequency of the relaxation oscillator, a set of capacitors of known capacitances, an electrical blackbox and a battery.

Caution: Check the voltage of the battery and ask for a new one if the voltage is less than 9 V. Do not forget to switch on.

TABLE 1 Nominal Capacitance values

Code	Capacitance value (pF)
33J	34 ± 1
68	68 ± 1
82J	84 ± 1
151	150 ± 1

Part 1. Calibration

Perform the measurement of f using the given capacitors of known capacitances. Draw appropriate graph to find the value of α and C_s . Error analysis is not required. [3.0 points]

Part 2. Determination of geometrical shape of a parallel plate capacitor

[6.0 points]

Given the three possible geometrical shapes as Pattern I, Pattern II and Pattern III as follows:

For each pattern, draw qualitatively an expected graph of C versus the positions of the upper plate but label the x-axis. Then, perform the measurement of f versus the positions of the upper plate. Plot graphs and, from these graphs, deduce the pattern of the parallel plate capacitor and its dimensions (values of b and w). The separation d between the upper and lower plates is 0.20 mm. The dielectric sheet between the plates has a dielectric constant $K=1.5$. The permittivity of free space $\epsilon_0 = 8.85 \times 10^{-12} \text{ Fm}^{-1}$. Error analysis is not required.

Part 3. Resolution of digital calipers

[1.0 point]

As the relative position of the parallel plates is varied, the capacitance changes with a pattern. This set-up may be used as digital calipers for measuring length. If the parallel plate capacitor in this experiment is to be used as digital calipers, estimate from the experimental data in Part 2 its resolution: the smallest distance that can be measured for the frequency value $f \approx 5 \text{ kHz}$. An error estimate for the final answer is not required.

2. Mechanical Blackbox: a cylinder with a ball inside

A small massive particle (ball) of mass m is fixed at distance z below the top of a long hollow cylinder of mass M . A series of holes are drilled perpendicularly to the central axis of the cylinder. These holes are for pivoting so that the cylinder will hang in a vertical plane.

Students are required to perform necessary nondestructive measurements to determine the numerical values of the following with their error estimates:

- i. position of centre of mass of cylinder with ball inside.

Also provide a schematic drawing of the experimental set-up for measuring the centre of mass. [1.0 points]

- ii. distance z [3.5 points]

- iii. ratio $\frac{M}{m}$. [3.5 points]

- iv. the acceleration due to gravity, g . [2.0 points]

Equipment: a cylinder with holes plus a ball inside, a base plate with a thin pin, a pin cap, a ruler, a stopwatch, thread, a pencil and adhesive tape.

x_{CM} is the distance from the top of the cylinder to the centre of mass.

R is the distance from the pivoting point to the centre of mass.

Caution: The thin pin is sharp. When it is not in use, it should be protected with a pin cap for safety.

Useful information:

1. For such a physical pendulum, $M + m R^2 + I_{CM} \frac{d^2\theta}{dt^2} \approx -g M + m R\theta$, where I_{CM} is the moment of inertia of the cylinder with a ball about the centre of mass and θ is the angular displacement.
2. For a long hollow cylinder of length L and mass M , the moment of inertia about the centre of mass with the rotational axis perpendicular to the cylinder can be approximated by $\frac{1}{3} M \left(\frac{L}{2}\right)^2$.
3. The parallel axis theorem: $I = I_{\text{centre of mass}} + \mathfrak{M}x^2$, where x is the distance from the rotation point to the centre of mass, and $\mathfrak{M}$ is the total mass of the object.
4. The ball can be treated as a point mass and it is located on the central axis of the cylinder.
5. Assume that the cylinder is uniform and the mass of the end-caps is negligible.
